1 Introduction

The Central Processing Unit (CPU) 6502 was introduced at 1976 by Commodore Computers. It is an 8 Bit processor which is well known worldwide. The also most known computer system in the 70s/80s was the APPLE based on this famous 6502.

In this century building of little computer systems based on an 8 Bit architecture is easier than ever before. Many CAD/CAM tool are existing on the market to give you help to do this job.

In the last decade the technology give us more and more possibilities to reach our dreams – higher, faster, wider. FPGA's (Field Programmable Gate Arrays) and CPLD's (Complex Programmable Logic Devices) are coming up. They shortening the time of development, simulation and verification of such systems dramatically. On the other hand stands the rising complexility of designs and well knowing of desired description languages – VHDL (Very high scale integration Hardware Description Language) or Verilog.

Many operations and functions of computer tasks aren't need really the power of "modern" processors today like Intel's Pentium. Nevertheless it is not usable – some times also impossible - to build simple systems with discrete IC's. The necessity of flexibility compel us the using of high tech parts and tools...to build a "simple" system.

The using of standard IP's (Intellectual Properties) is the key to reach that goal.

Now talking about the specification of the **6502 True Cycle Core IP**. Written in VHDL but developed with Mentor's HDL Designer. The 6502 is very easy to handle for people were have experience with other cpu's. Also suitable for beginners who will learning to build her own first cpu system.

2 Architecture

The following figure shows the internal architecture of the Commodore's 6502.

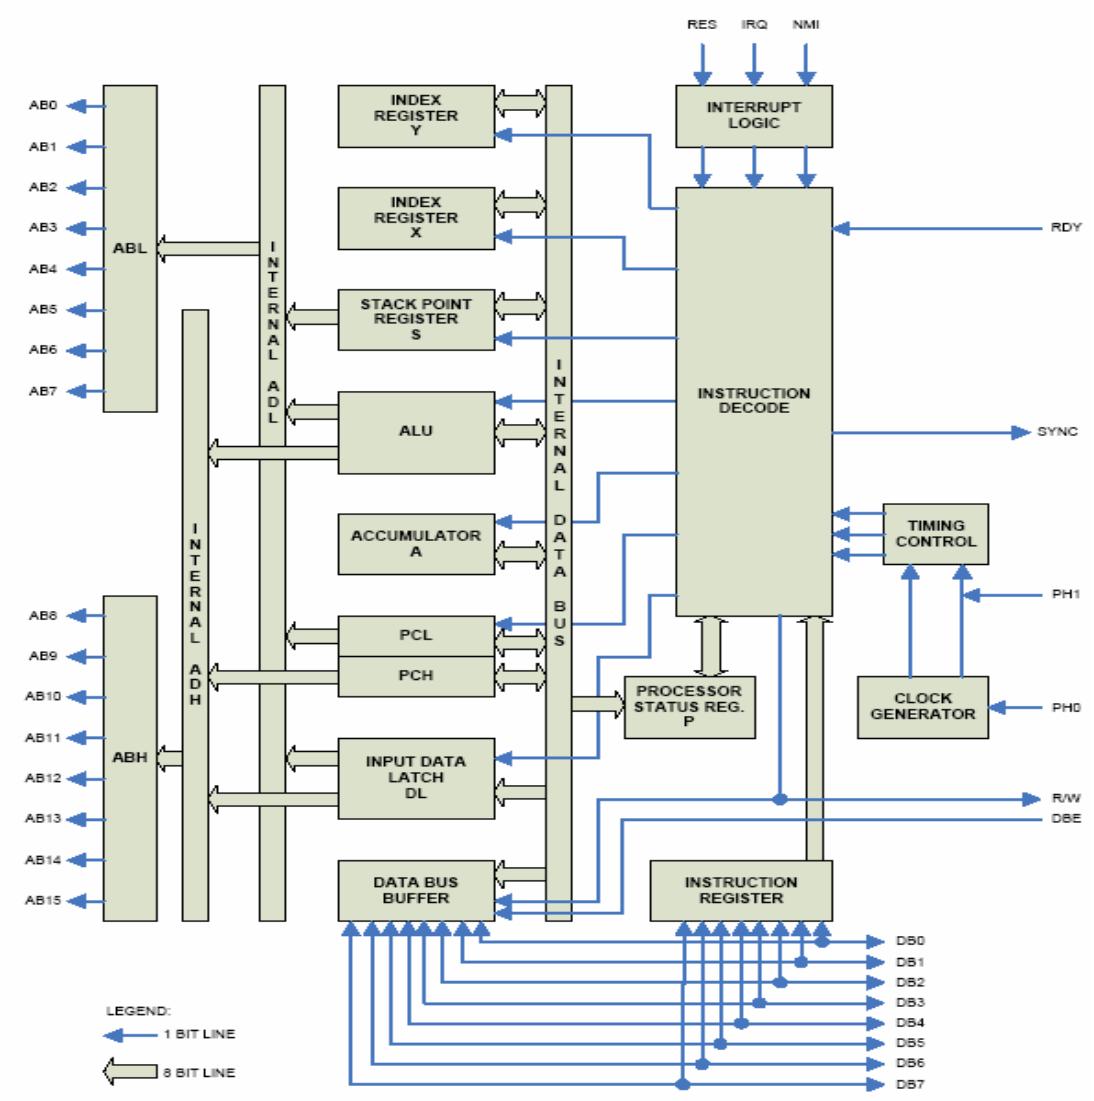

Figure (1): 6502 architecture

First, for more clearance and better understanding of the **6502 True Cycle Core IP** let me summarize the most important quality of Commodore's 6502.

This architecture based on asynch logic. The two phase clock is a special attribute of that. The Data Bus is only active while clock phase PH1 is "1" for reading and writing (PH0 is "0"). All transfers of data are occur at active phase of PH1.

The whole 6502 is fully statically, so all registers holding her values if the clocking will be going to D.C. Internally all operation of 16 Bit are splitted into two 8 Bit busses. This is very interesting and causes one more clock cycle in some operations (see “PCL”, “PCH” -> Program Counter Low/High) which can operate over page boundaries.

Address lines are 16 Bit wide. 65.536 addresses for byte access are possible. There are no differences exist between memory and I/O cycles. All I/O devices must be connected via memory mapped I/O. The mnemonics are also all the same for both. The usage of address space is normally organized form top to the button “ROM – I/O – RAM” (0xFFFF – 0x0000).

Only one pin R/$\overline{W}$ controls the read and write operations.

The 6502 can hold in every cycle – except write cycles - by applying RDY. So wait states can be generate by using RDY.

There are two interrupts $\overline{IRQ}$ and $\overline{NMI}$. $\overline{IRQ}$ is mask able, $\overline{NMI}$ is not. Note that $\overline{RES}$ is internally handled as an interrupt, but is resetting the 6502 to the starting point of operation at vector address 0xFFFF. Every interrupt has its own vector which can point elsewhere to the 16 Bit address space. The vectors are located from 0xFFFF to 0xFFFA.

The Stack Pointer is 256 Bytes deep and is hard-wired to 0x01FF (internally 0x0200 –0x01FF going to the address bus) for the first memory location and grows downward to 0x0100. Decrementing again will produce a wrap around back to 0x01FF.

Arithmetical operations like ADC and SBC can handle binary values from 0-255 and decimal values from 0-99 without using other op codes. Only one user changeable bit into the Status Register determine the exact arithmetic mode of that operations.

The 6502 generally operates into a pipeline mode. That means that a finish of an OP code falls every time into a fetch cycle of the next OP. This save one clock cycle

Every operation consume between two and seven clock cycles.

To build an useful und backward software and hardware compatible VHDL Core for the 6502 many unavoidable changes may be forced to simulation and verification before any real core will be made.

The requirements:

- Vendor indepent for implementation in any FPGA
- True Cycle for all operations as described in original publications
- No “Mixed Mode” – Only 6502, not 65C02 -> for performance and area
- No fantastic or useful extensions – as like the original 6502 as possible
- Don’t implement the “undocumented OP’s” at this time -> goodie for future releases
- Only one clock
- Full synch design
- Operating speed up to 60 MHz – or higher
- Easily to change for future requirement – building variants
- The activity on data and address busses since the execution of OP codes is not forced to be like the original – may be or may be not.

The design based on finite state machines (fsm). Every OP code has its own fsm. Some registers are for internally use only and stores temporally values. These registers are not accessible by the programmer.

Some fsm’s own registers for internally use and don’t share this registers with other fsm’s. This help to decrease fan-in and increase performance.

The next picture shows the hierarchical structure of the R6502 IP core.

TAX

Operation: Transfer accumulator A to index X (A → X)

Addressing Mode	Assembly Language Form	OP CODE	No. Bytes	No. Cycles	N	V	E	B	D	I	Z	C
Implied	TAX	AA	1	2	√	-	-	-	-	-	√	-

Table (51): TAX – Short Reference

Example Implied (assume A=$5D):

Address	Bytes	Mnemonic	
$9000	AA	TAX	;
$9001	…	*next OP*	; X is now $5D, N=0, Z=0

TAY

Operation: Transfer accumulator A to index Y (A → Y)

Addressing Mode	Assembly Language Form	OP CODE	No. Bytes	No. Cycles	N	V	E	B	D	I	Z	C
Implied	TAY	A8	1	2	√	-	-	-	-	-	√	-

Registers

This section specifies all internal registers. It should completely cover the interface between the core and the host as seen from the software view.

List of Registers

Name	Address	Width	Access	Description

Table 1: List of registers

Register 1 – Description

(You shall choose the style of register you prefer. Do not use both options in one and the same document.)

Bit #	Access	Description

Reset Value:

Clocks

This section specifies all the clocks. All clocks, clock domain passes and the clock relations should be described.
